What is radar altimetry?

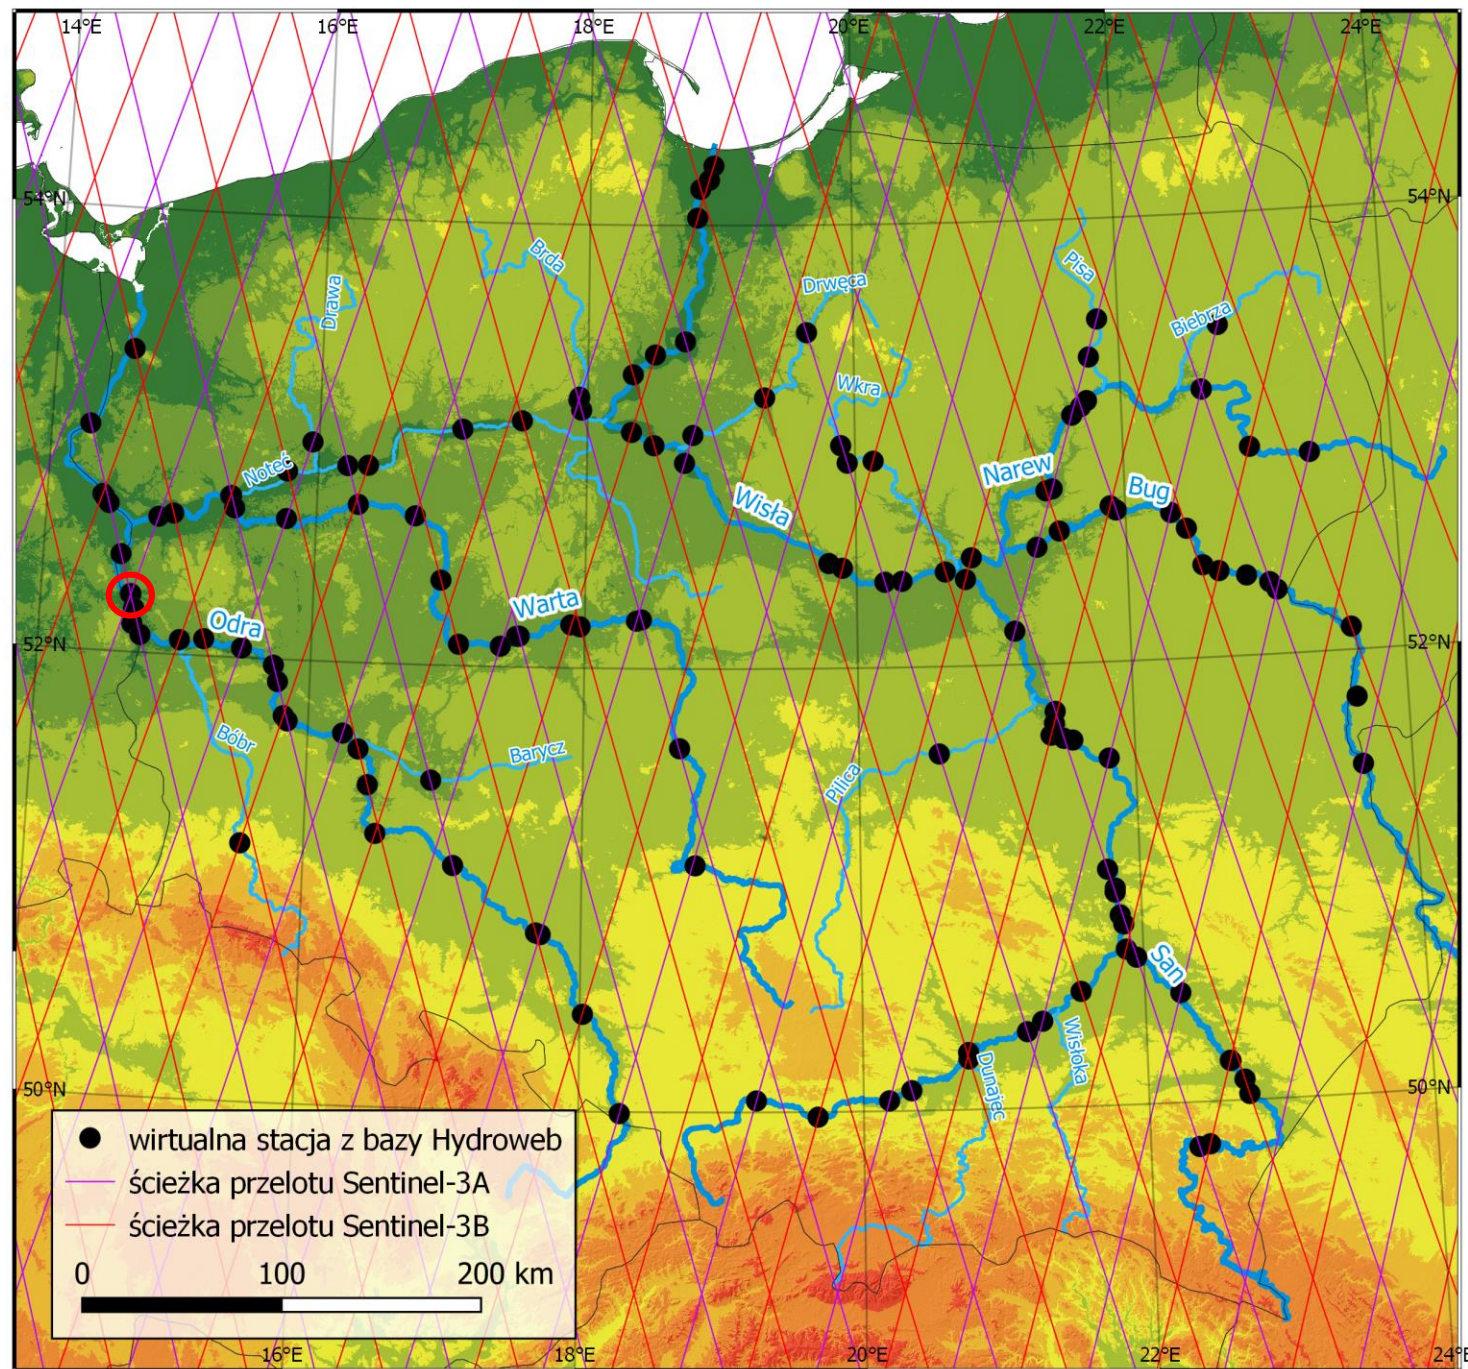

- Technique of measuring height
- Radar altimeter emits signal to Earth and receives the echo after its reflection
- After detecting the echo from a water surface, it is possible to measure the water level w.r.t. a vertical system, i.e. geoid or ellipsoid

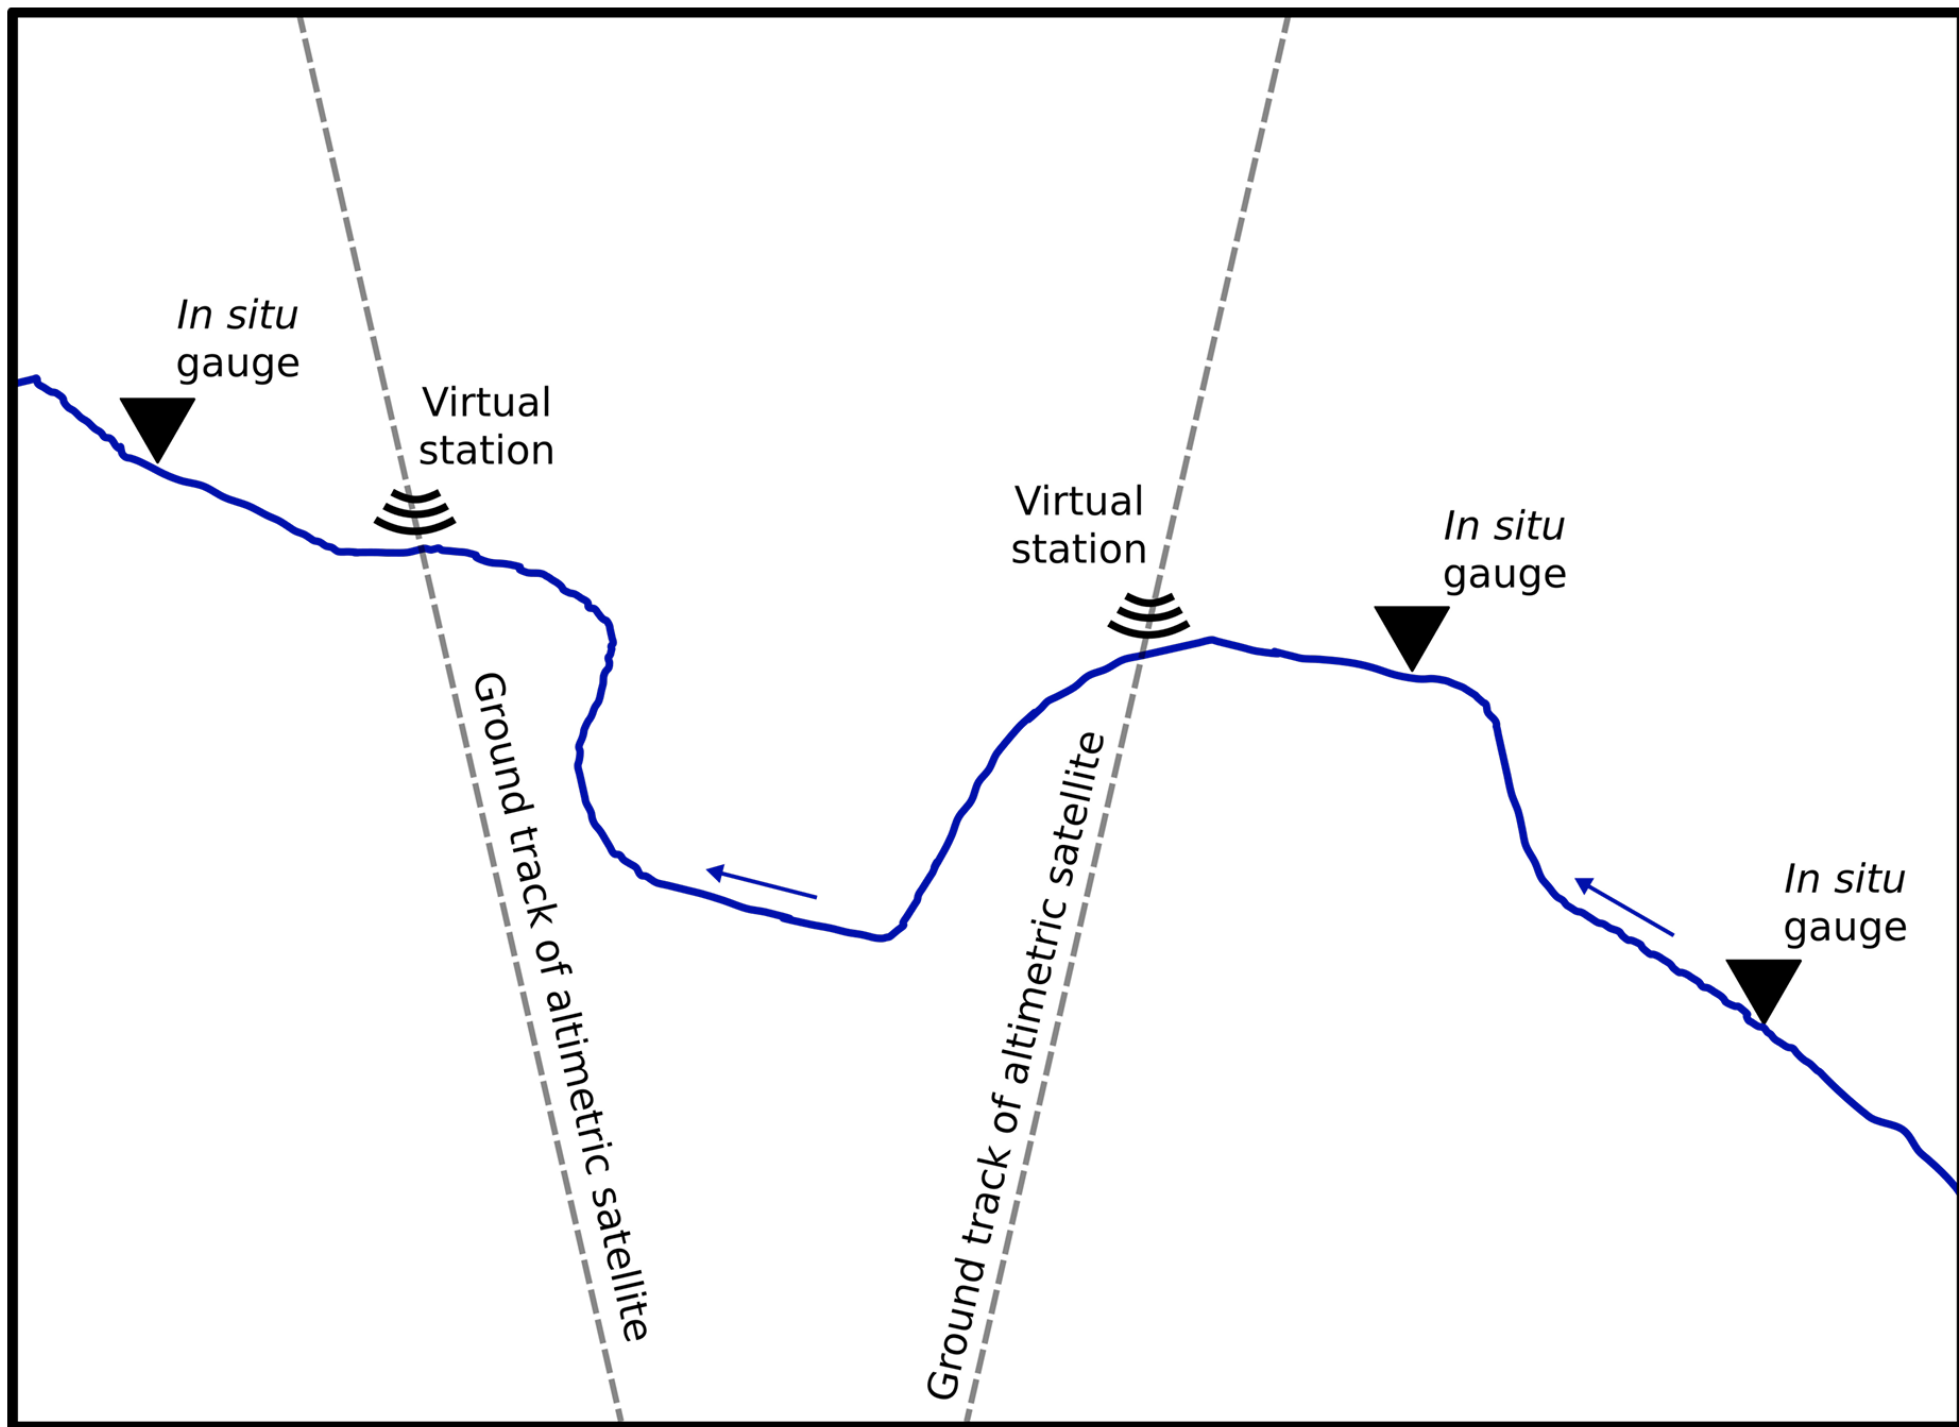

(Martins et al., 2021)

What is radar altimetry?

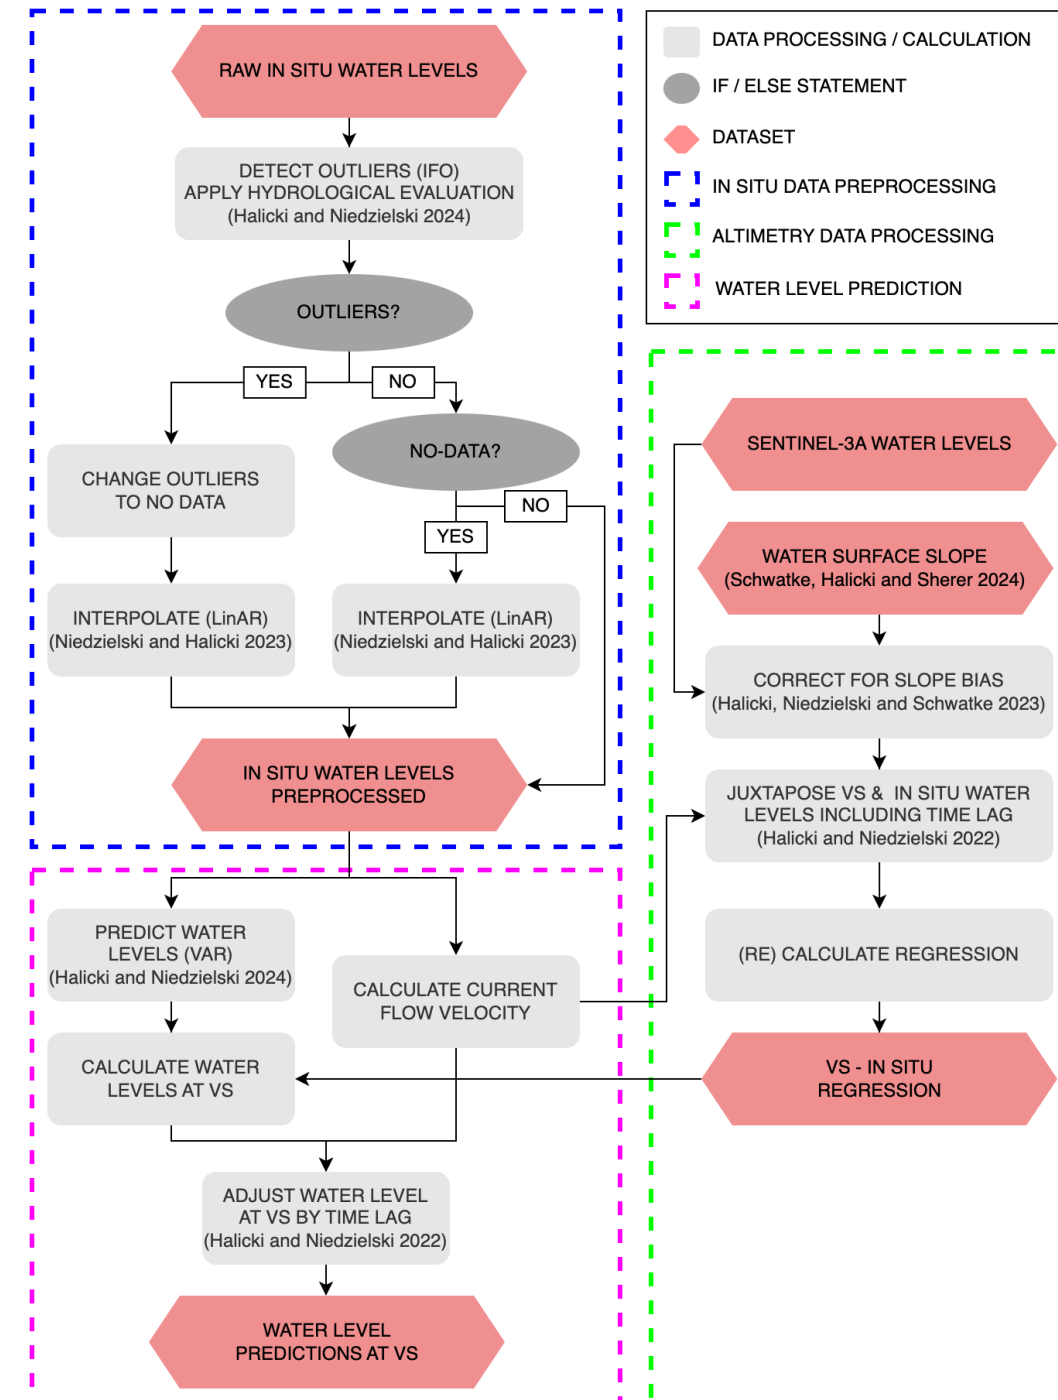

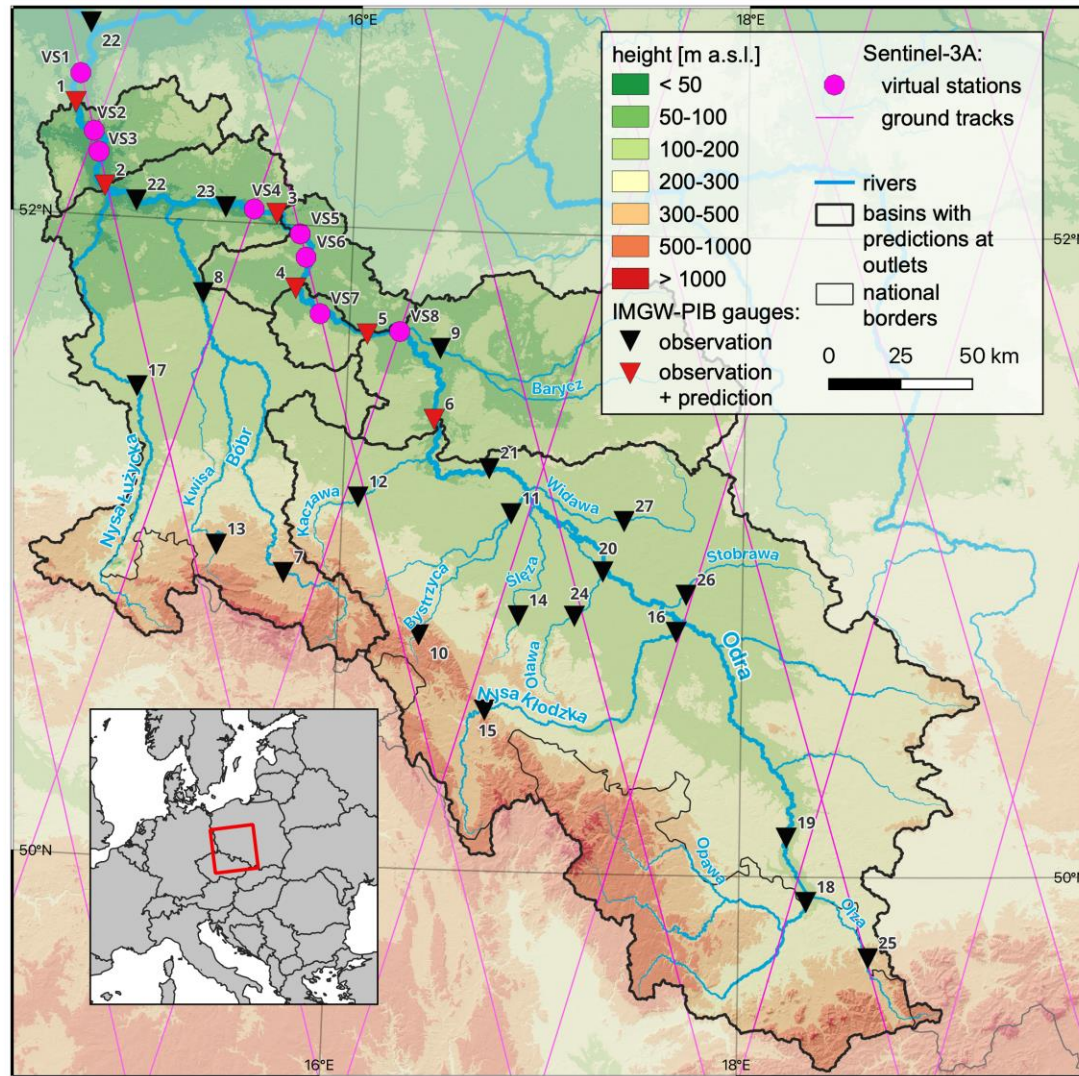

- Due to the nadir-looking nature of altimetry, water levels are available only at virtual stations (VS), i.e. crossings of satellite path and riverbed.
- Poor temporal resolution (27 days for Sentinel-3)
- Accuracy: ± 20 cm

Workflow overview

Transferring WL from gauge to VS

1. Juxtaposition of altimetry and water level gauge measurements
2. Determination of linear regression between observations.
3. Conversion of forecasts from gauges to virtual stations.
4. Time shift of forecasts.

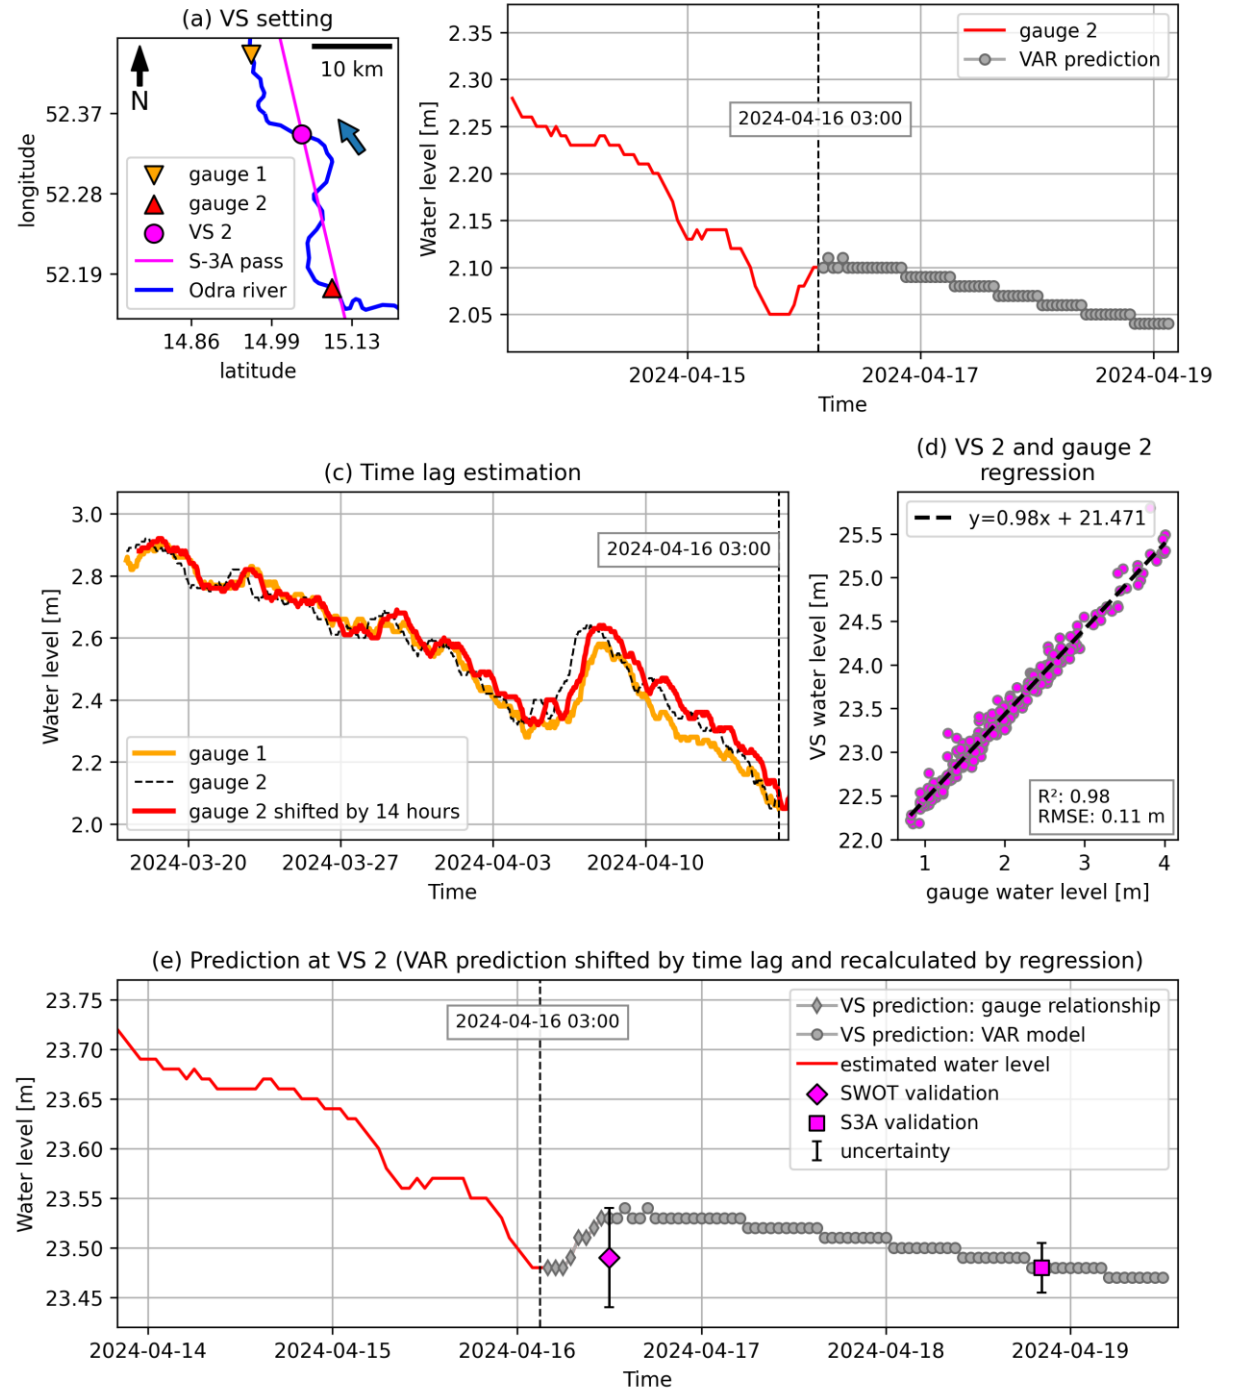

Time lag estimation

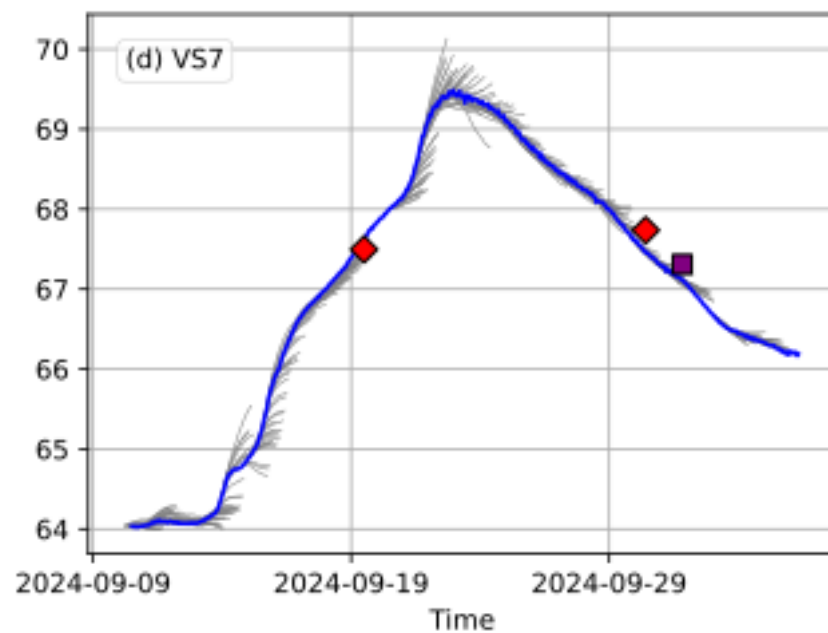

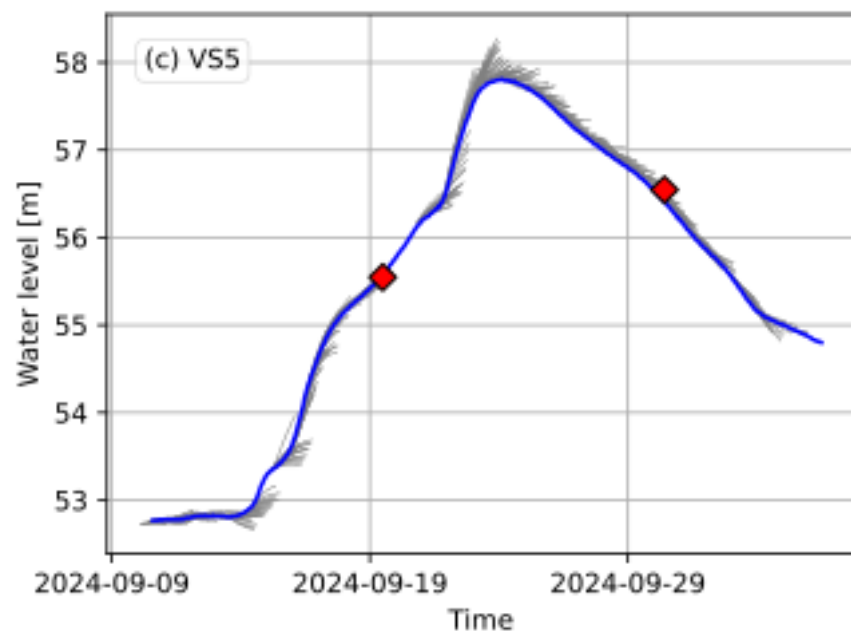

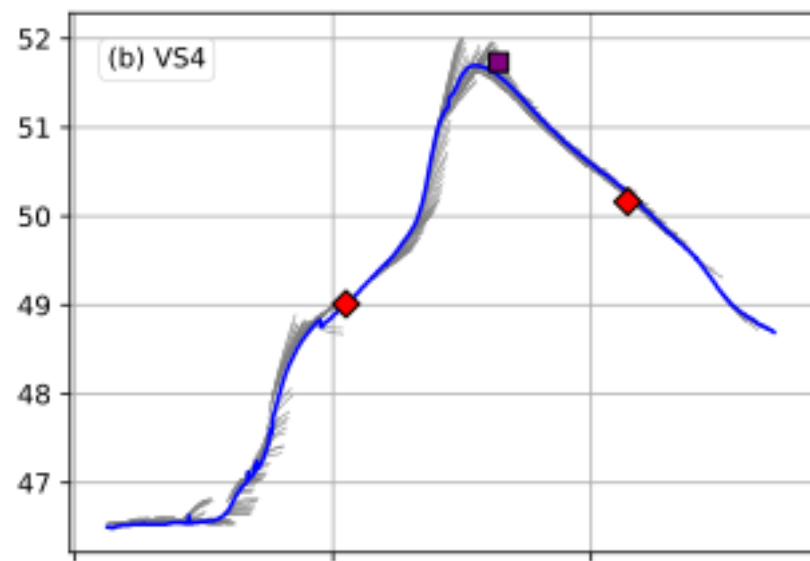

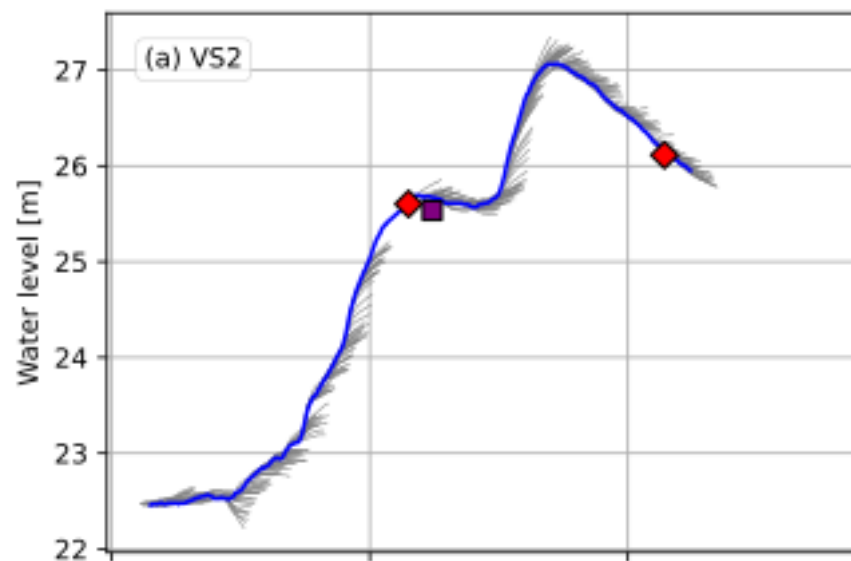

1. Determination of such an offset between neighbouring gauges, for which the correlation of the hydrographs will be the highest
2. Water velocity = distance/time (offset)

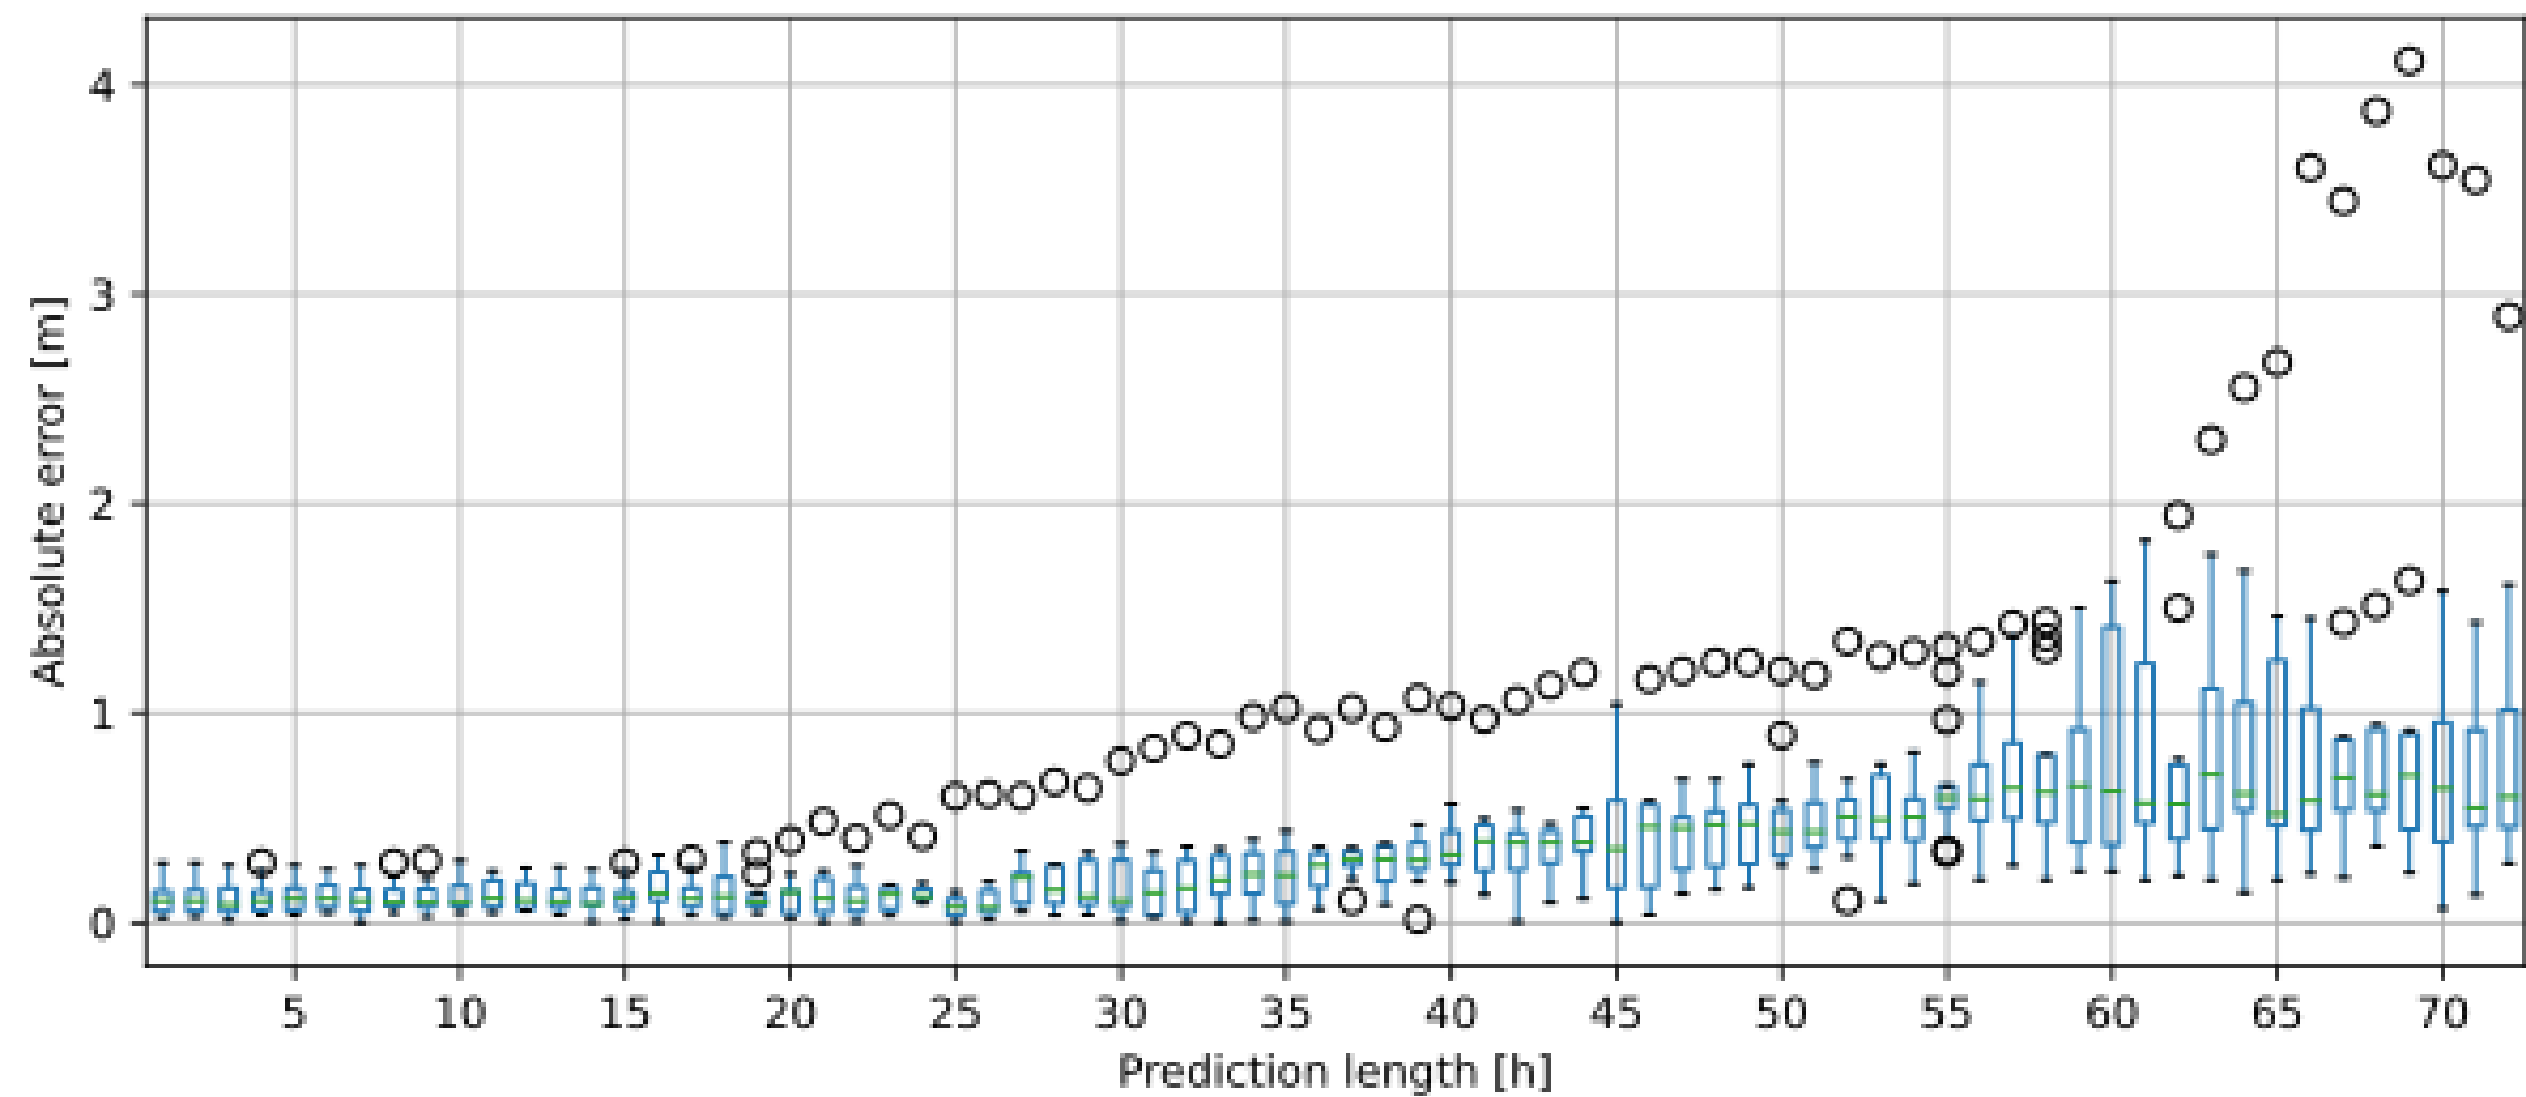

Transfer procedure

- Setting of the VS
- Prediction based on Vector Autoregressive Model (VAR) for gauge 2
- Time lag estimation based on gauge data from previous month
- Current VS 2 – gauge 2 regression
- Transfer of VAR prediction (b) to VS2 based on regression coefficients and time lag

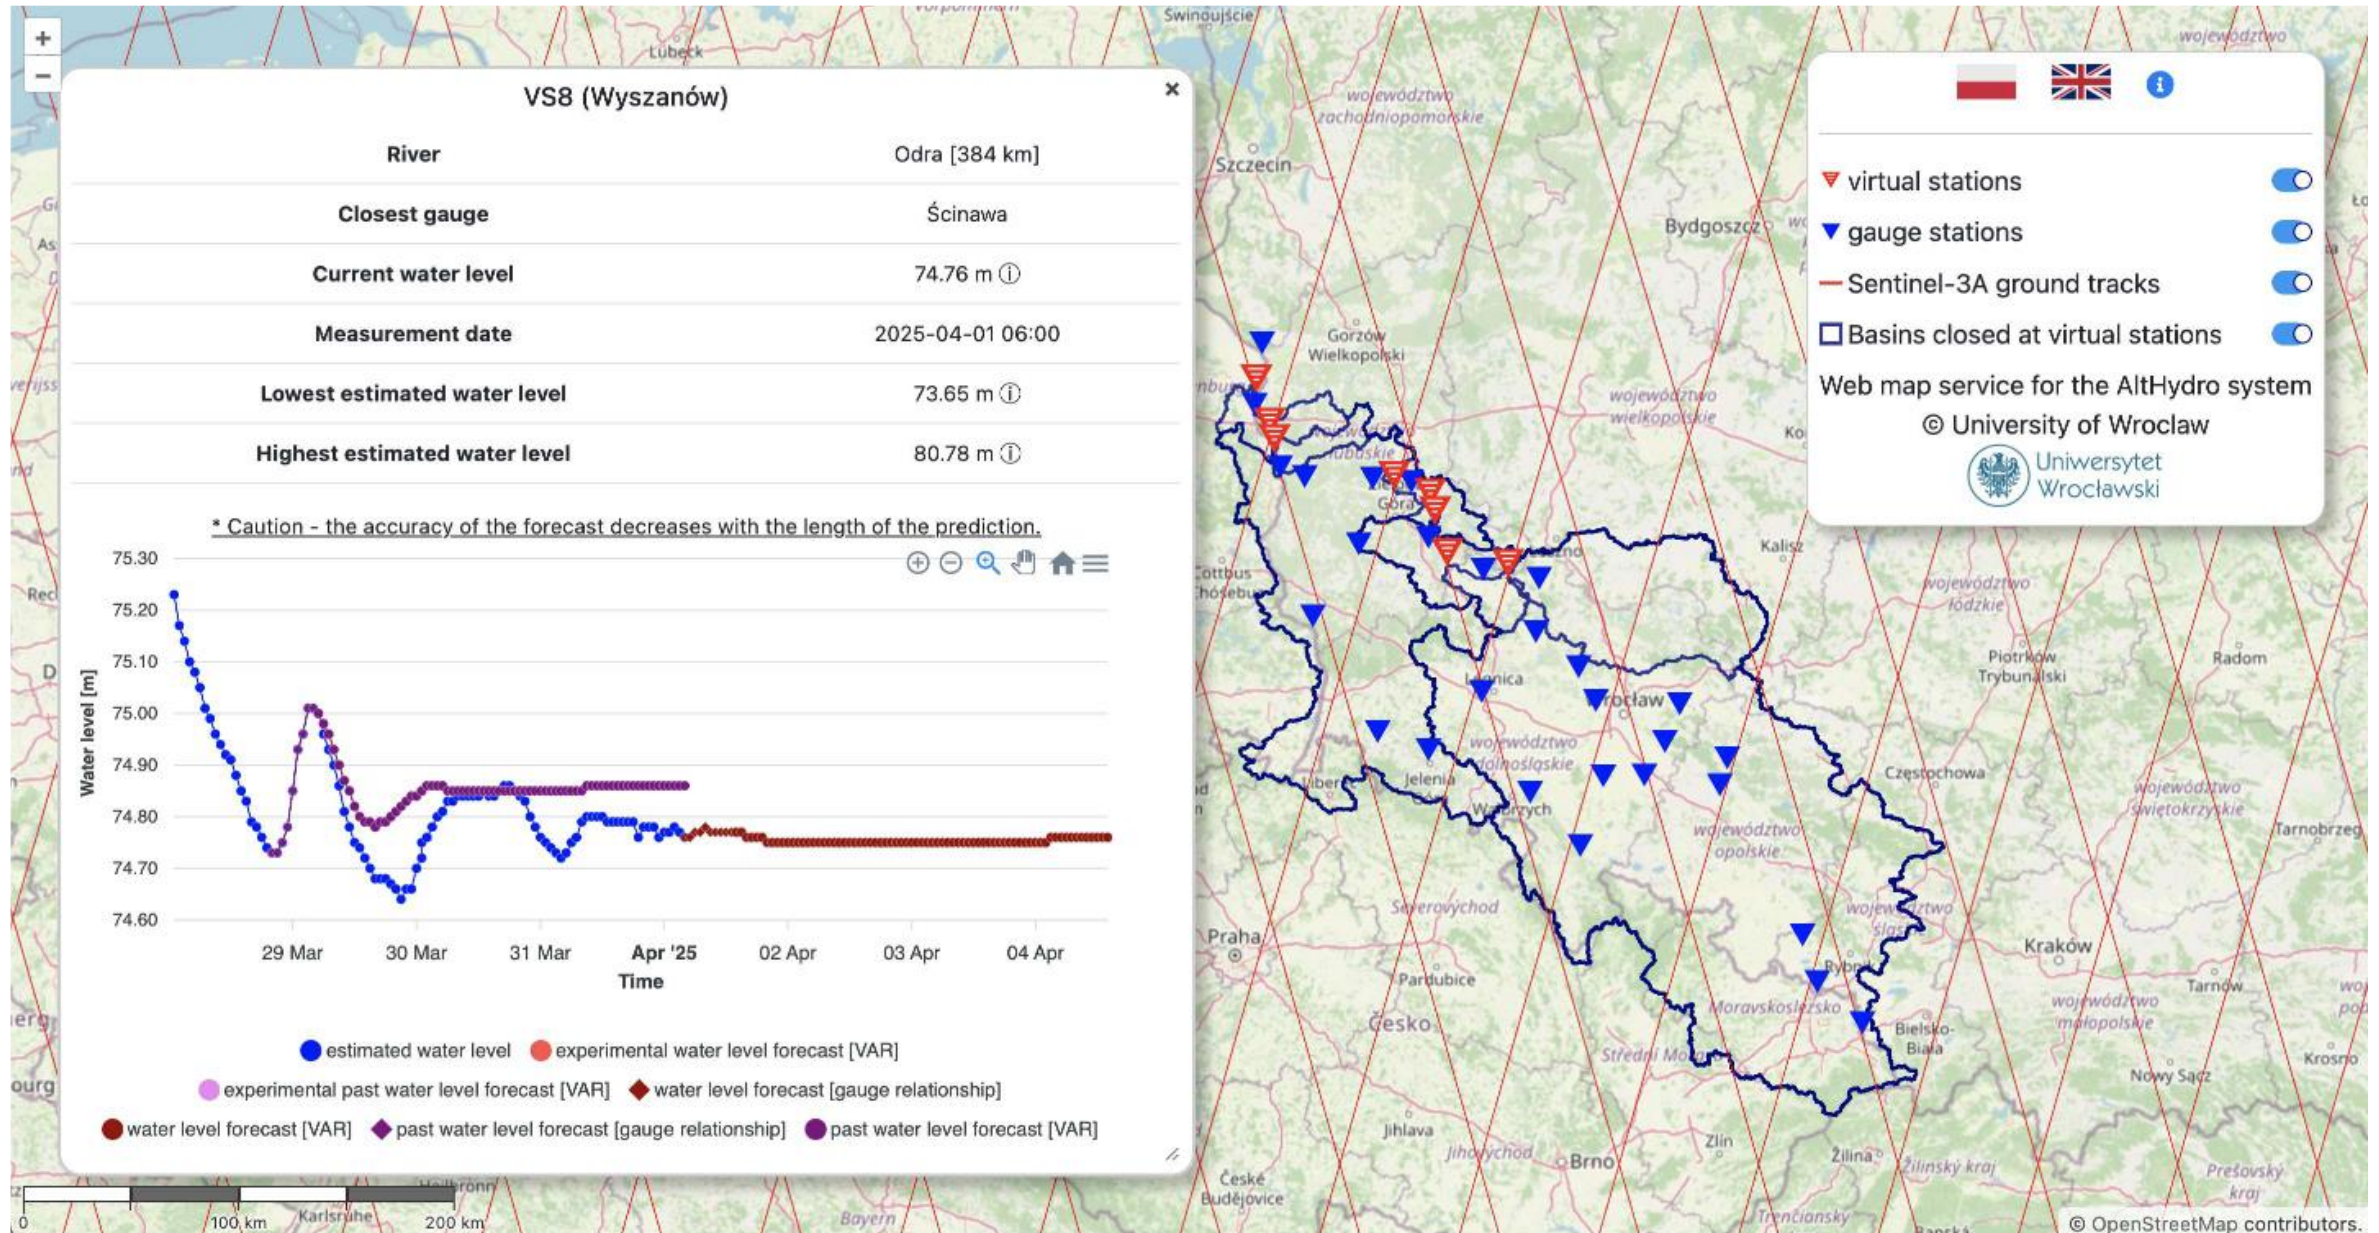

Real time predictions at virtual stations:
